Topic 2.1.2

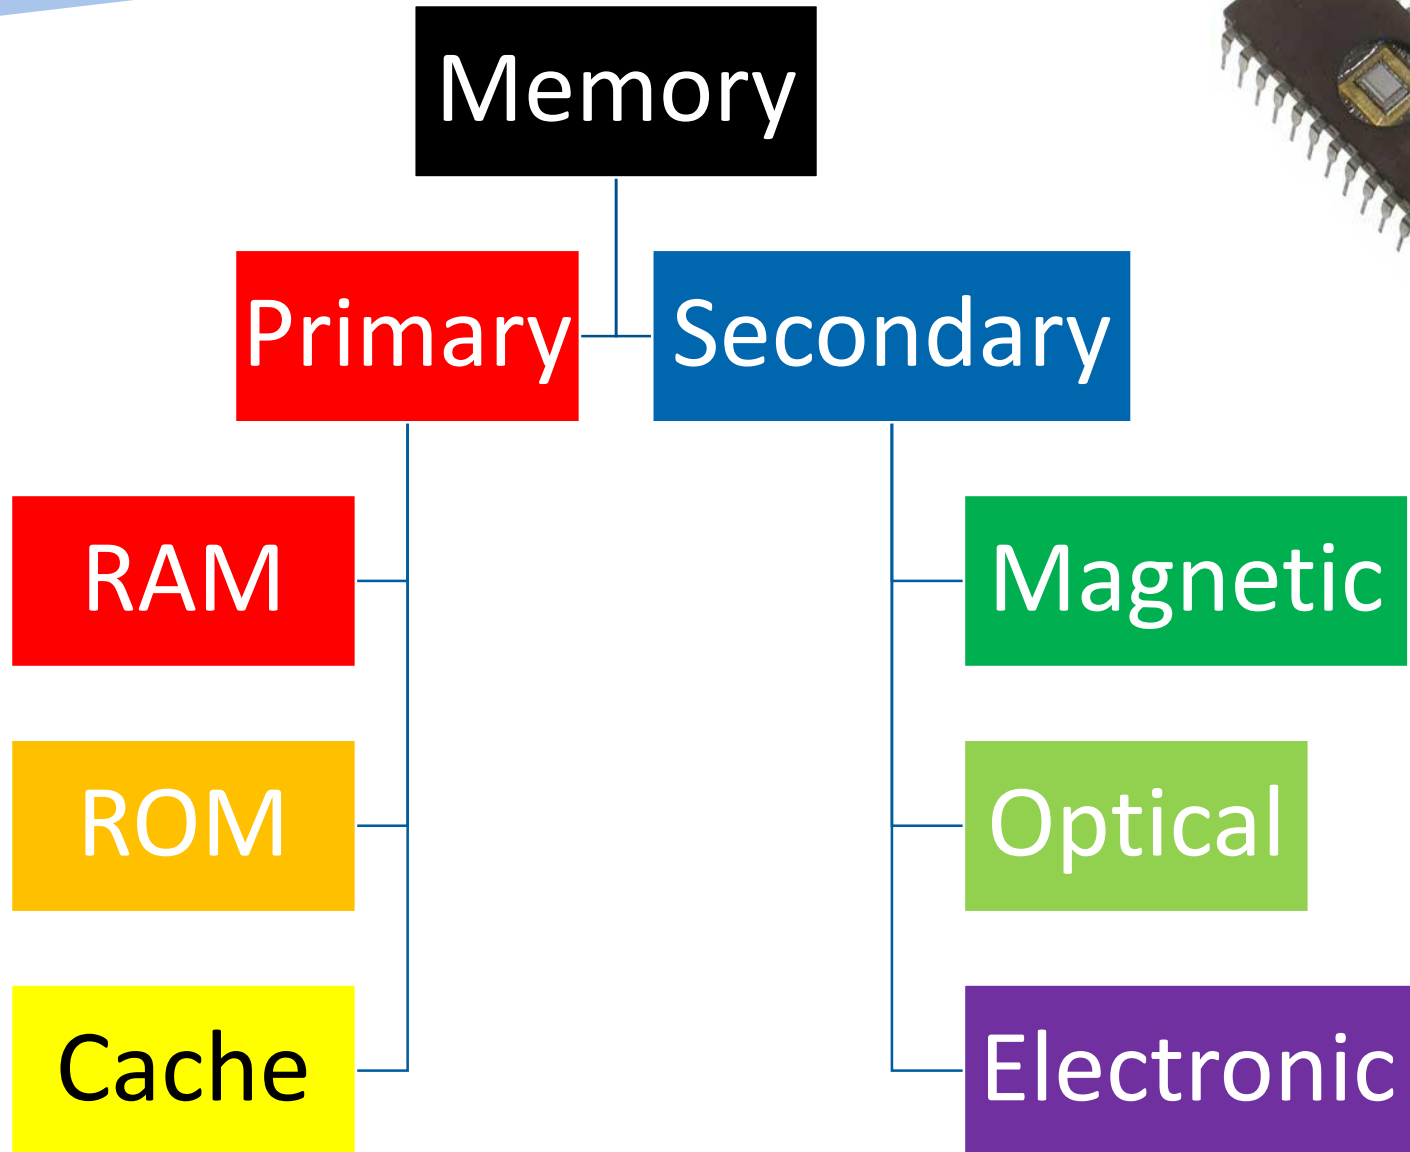

Describe **primary memory**.

Simplified model: CPU, RAM

Primary memory = RAM

As **RAM** is so important, it is often referred to as **primary memory** (even though it is actually only a branch of primary memory, alongside the cache and ROM).

In an exam/test, if you see *memory*, unless explicitly stated otherwise, it would normally be referring to **RAM**.

RAM = Random Access Memory

- Contains the **data** and **instructions** the computer has loaded since starting up and everything the user has opened/loaded.
- Is **volatile** = loses its contents if power is lost
- Has a special link to the CPU (via busses)

ROM = Read Only Memory

- Originally its contents were static (hence '**read only**') and could not be changed – not true any more (flash upgrades).
- **Non-volatile** = does not lose its contents if power is lost
- Stores the **BIOS** (Basic Input Output System) – a small program that allows the computer to know what to do to find the operating system to 'boot' the computer after power is restored.

RAM	ROM
Volatile	Non-volatile
Contains user's programs and data that has been loaded since 'booting up'	Contains the BIOS
Usually upgradeable, can be increased	Usually part of motherboard, difficult to upgrade

RAM - ROM
